DEPOSITS OF CALCIUM CARBONATE (LIMESCALE)

Limescale accumulates as soon as hard water flows through pipes. It represents a foreign body on the wall of the pipes, creating massive problems. Its destructive effect on machine parts and equipment that come into contact with water is not to be underestimated either.

Typical problems that can be caused by limescale:

- Blocked pipework
- Loss of water pressure
- Build-up of rust on pipes that can lead to corrosion
- Bacterial growth in drinking water and process water
- Recurring repairs
- Loss of energy in hot water circuits, resulting in higher heating costs
- A need for aggressive cleaning agents, resulting in high costs
- Faulty machinery – declining productivity caused by more frequent maintenance

"A heating rod with only one millimetre of limescale incrustation results in 10% higher energy costs. The energy consumption increases by over 40% with one centimetre of incrustation."

An electromagnetic field is generated by an induction pipe in the **STAP** process. So-called submicroscopic clusters of the ions dissolved in the water are formed by stimulation of the coil current of the electromagnetic field induced by the **STAP** process.

These clusters act as crystallisation nuclei and – especially when the fluid is heated up – cause calcium carbonate to precipitate in the form of suspended particles. This represents a process that competes with calcium deposition on the inner walls of pipes, boilers and machine parts.

As the **STAP** process continues, more ions from the water accumulate on these crystallisation nuclei caused by precipitation, which can lead to a considerable growth of these suspended particles, depending on the duration of the electromagnetic effect.

This process takes place throughout the entire volume of water. The crystal nuclei thus formed act as crystallisation centres in places of raised supersaturation and, thanks to their growth, succeed in significantly reducing supersaturation. In addition to transforming the molecular structure of constituents – for instance in calcitic molecules – the **STAP** process is also capable of preventing further deposits.

The crystallisation nuclei formed bind more calcium from the limescale deposits dissipating it as amorphous precipitation. This process continues until the surface is free of deposits. A thin protective layer is formed once the limescale deposits have been dissolved, which is produced by the amorphous surface of the crystals reacting with the metallic surface. As soon as the thin protective layer has formed it no longer grows.

I would be happy to confirm that the scientific findings we have conducted by means of transmission electromicroscopy included in the images and text in your product data sheet, are correct and have been accurately reproduced.

WE HAVE THE RIGHT SOLUTION FOR EVERY PROBLEM

profi® 800

Induction pipe

Aqua-Split

Filter unit

mobile-400®

Our product range can be easily combined to deal with any situation in your building or business. The kit always comprises an **-profi® control unit** – with the size based on the imperial size of your water pipe – and one of two induction pipes. The induction pipe is replaced by a turbo pipe in industrial applications, which also enables larger volumes of water to be successfully treated.

The **filter unit included with the Aqua-Split** is another key component of the system. This system generates a high level of turbulence and needs to be integrated if you use catering coffee machines, dishwashers, ovens and convector ovens in your company, as it protects these sensitive units very effectively against limescale.

We have developed the **KF-mobile-400®** specifically for premises that are only rented, such as petrol stations, food stands or transport solutions. It is simple to integrate, as all the components, including the control unit and induction pipe, are housed within a splash water-proof case.

THE -PROFI-® IN USE

Apartment block with 10 residential units, Würzburg region, Property management: Eichhorn Immobilien GmbH

Industrial business, Stuttgart
The turbo pipe always replaces the induction pipe wherever larger volumes of water are moved.

organisation – planning – execution

The water is "denser" (molecular structure) and the flow velocity has decreased since we fitted the profi® 800. It is easier to handle the water, meaning that we also consume less water.

As there are no longer air bubbles in the water, it freezes more quickly – saving energy and labour time. The ice is harder, more compact and more stable.

We have less work and are really satisfied. The treated water is only used in the ice rink to top up the ice-making machines to build up the ice.

The profi® 800 has been installed in the Vita Alpina since 2013. Before it was commissioned, the pipes were very heavily calcified. The profi® 800 has dissolved the caked limescale and no additional deposits have been formed. There is no longer a need for maintenance work.

Installing the system means that we also save heating energy. The profi® 800 has been working totally maintenance-free since it was installed.

6) Zusammenfassung

a) Die Auskristallisierung der mit dem STAP-Verfahren behandelte Wasserprobe

- enthält im wesentlichen amorphe Bestandteile der Element Ca, C, O (amorphes Calciumcarbonat ACC), die kettenförmig verbunden sind
- und
- enthält vereinzelt eingebettete Calciumcarbonatkristalle, die maximal 200 nm groß sind.

b) Die Auskristallisierung einer Probe desselben unbehandelten Wassers

- enthält 2 ... 7 µm große Partikel der Element Ca, C, O mit hohem Kristallisationsgrad (kristallines Calciumcarbonat Calcit, Argonit oder Vaterit)

Bei den Untersuchungen handelt es sich nicht um eine einzelne punktförmige Analyse, sondern die Ergebnisse lassen sich auf der gesamten Probe erzielen.

Mit diesen Untersuchungen ist nachgewiesen, dass das STAP-Verfahren die kristalline Struktur der Auskristallisierungen von Wasserproben eindeutig ändert, indem fast alle Kristallstrukturen amorphisiert werden.

Eine differenzierte Analyse der auftretenden Calciumcarbonatkristalle war nicht Gegenstand der Untersuchung.

Prüfbericht

Auftraggeber: Herr Sebastian Sterff
Pro Terra Bauunternehmungs- und Immobilien - gesellschaft mbH
Anspachstraße 46
D-97070 Würzburg

Probe: 2 Wasserproben "unbehandelt" und "nach STAP-Verfahren behandelt"
geliefert durch Ingenuum Service Kötter, Rosenheim

Messort: Labor für Transmissionselektromechanikoptik
Zentraleinrichtung Elektromechanikoptik (ZELMI)
Technische Universität Berlin (TU Berlin)
Straße des 17. Juni 135
10623 Berlin

Die Untersuchungen erfolgten im März 2009 im Auftrag von Mr. Sebastian Sterff und der Firma Ingenuum AG.

Dr. D. Berger 2009 TU-Berlin Prüfbericht Sterff 2019.doc 16. September 2019 Seite 13 von 13

Summary and advantages:

- Prevention of limescale formation throughout the water network.
- Degradation of previously formed limescale deposits
- Formation of a protective layer on the inner wall of the pipe
- Reduction of energy costs
- No use of chemicals necessary
- Maintenance-free operation of the system
- No maintenance costs
- Small installation size
- Very low power consumption
- Noiseless operation of the system
- Offers unchanged good drinking water quality
- More compatible water for skin and hair
- Better taste for beverages, e.g. coffee
- Confirmed effect of the Technical University in Berlin, Germany
- Guarantee of 2 years
